

# LOCKIN EDUCATION @ BUGIS

H2 Biology

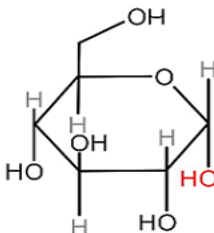

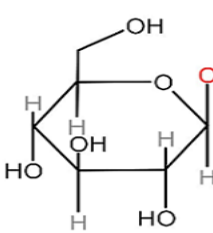

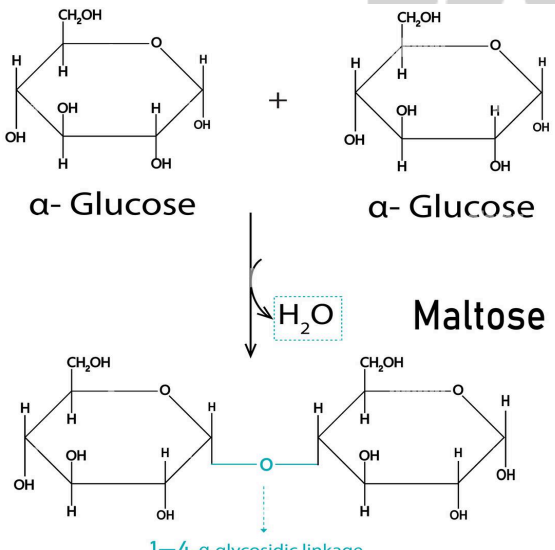

## Summary Notes Revision Package

“To study Biology is to study life itself — and to understand it is to think with precision.”

Prepared by: Wayne, Bio Tutor

## Carbohydrates

Carbohydrates: generally (CH <sub>2</sub> O) <sup>n</sup>	
<p>Monosaccharides: C<sub>6</sub>H<sub>12</sub>O<sub>6</sub></p> <div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  <p>Alpha-glucose</p> </div> <div style="text-align: center;">  <p>Beta-glucose</p> </div> </div> <p>Difference lies in position of -OH group on <b>Carbon-1</b></p>	<p>Features</p> <p><u>Glucose</u> ; <u>Galactose</u> ; <u>Fructose</u>          → All are <b>reducing sugars</b> due to free <b>carbonyl group (C=O)</b></p> <p>→ <b>Small size</b> &amp; have multiple <b>hydroxyl groups (-OH)</b> and can form <b>hydrogen bonds with water</b> ;  <b>Readily soluble in water!</b></p> <p><u>Solubility</u>: how well something can <b>INTERACT</b> with water (Interact means more than just H-bonds; it can mean ionic interactions, van der waals, etc.)</p>
<p>Disaccharides: C<sub>12</sub>H<sub>22</sub>O<sub>11</sub></p> <div style="text-align: center;">  <p>α- Glucose + α- Glucose → Maltose + H<sub>2</sub>O</p> <p>1-4-α-glycosidic linkage</p> </div>	<p>Features</p> <p>Glucose + Glucose → <b>Maltose</b> [GGM]          Glucose + Galactose → <b>Lactose</b> [GGaL]          Glucose + Fructose → <b>Sucrose</b> [GFS]          =&gt; All <b>reducing sugars</b> EXCEPT <b>Sucrose</b></p> <p>→ made up of 2 monosaccharides joined by a <b>glycosidic bond</b> formed between 2 monosaccharides by a <b>condensation reaction</b> that involves the <b>loss of a water molecule</b></p> <p>→ can be split back into their component monosaccharides via <b>hydrolysis reaction</b> where, with the <b>addition of one molecule of water</b>, the <b>glycosidic bond</b> can be <b>broken</b></p> <p>→ have many <b>hydroxyl groups (-OH)</b> which extend out of the ring which can form <b>hydrogen bonds with water</b> ;  <b>Readily soluble in water!</b></p>
<p>Polysaccharides: (C<sub>6</sub>H<sub>10</sub>O<sub>5</sub>)<sub>n</sub> → made up of many monosaccharides joined via <b>glycosidic bonds</b> formed between them by <b>condensation reactions</b> involving the <b>loss of water molecules</b></p>	

Polysaccharide	Starch	Glycogen	Cellulose
Function	<b>Plant storage</b> polysaccharide	<b>Animal storage</b> polysaccharide	<b>Plant structural</b> polysaccharide
Location	Stored as <b>granules</b> in <b>chloroplasts</b>	Stored in <b>liver</b> and <b>muscle cells</b>	<b>Cell walls</b> of plant cells
Monomer	Made up of <b><math>\alpha</math>-glucose</b> monomers	Made up of <b><math>\alpha</math>-glucose</b> monomers	Made up of <b><math>\beta</math>-glucose</b> monomers
Bond between monomers	In <b>amylose</b> : <b><math>\alpha(1-4)</math> glycosidic bond</b> links monomers;  In <b>amylopectin</b> : <b><math>\alpha(1-4)</math> glycosidic bond</b> links monomers within a branch and <b><math>\alpha(1-6)</math> glycosidic bonds</b> links monomers at branch points	<b><math>\alpha(1-4)</math> glycosidic bond</b> links monomers <b>within a branch</b> and <b><math>\alpha(1-6)</math> glycosidic bonds</b> links monomers <b>at branch points</b>	<b><math>\beta(1-4)</math> glycosidic bond</b> links monomers in a molecule
Orientation of monomer	All glucose monomers in the chain have the <b>same orientation</b>	All glucose monomers in the chain have the <b>same orientation</b>	Alternate $\beta$ glucose monomers <b>rotated <math>180^\circ</math></b> with respect to each other
Structure of each molecule	<b>Amylose</b> is a <b>helical</b> molecule while <b>amylopectin</b> is a <b>helical and branched</b> molecule	<b>Helical and branched</b> molecule, like amylopectin, but <b>more extensively branched</b>	<b>Long, straight chain</b>
Bonds between molecules	No <b>interchain</b> hydrogen bonding	No <b>interchain</b> hydrogen bonding	<b>-OH groups projecting outwards in both directions</b> allow <b>interchain</b> hydrogen bonding between parallel chains <b>→ forming microfibrils</b>

How the structures of starch and glycogen make them good <u>STORAGE</u> molecules	How the structure of cellulose makes it a good <u>STRUCTURAL</u> molecule
<p>1. Made up of many <b><math>\alpha</math>-glucose monomers</b> that <b>coil</b> to form <b>helices</b></p> <ul style="list-style-type: none"> <li>- Hence is a <b>large yet compact energy store</b> as many <b><math>\alpha</math>-glucose monomers</b> can be packed <b>per unit volume</b></li> <li>- Hence <b>most -OH groups</b> are involved in <b>intramolecular hydrogen bonding within the helix</b> and <b>few -OH groups</b> available for <b>hydrogen bonding</b> with water.</li> </ul> <p>→ Hence <b>starch/glycogen</b> is <b>insoluble in water</b> and the <b>osmotic potential</b> of cells are <b>unaffected</b> by its presence.</p> <p>2. Amylopectin and glycogen are <b>branched</b></p> <ul style="list-style-type: none"> <li>- Thus they have <b>multiple branch ends</b> which <b>hydrolytic enzymes</b> can work on. Hence <b>more glucose molecules</b> can be <b>released at the same time</b> and <b>more ATP</b> can be generated by respiration <b>per unit time</b>.</li> </ul>	<p>1. <b>Adjacent glucose units</b> are <b>inverted 180°</b> with respect to each other and hence form a <b>long, linear, unbranched</b> molecule with free <b>-OH groups projecting out in both directions</b> which can <b>hydrogen bond</b> with <b>-OH groups</b> of other cellulose molecules lying <b>parallel</b> to it and form <b>microfibrils</b>.</p> <ul style="list-style-type: none"> <li>- Hence <b>microfibrils</b> have <b>high tensile strength</b>.</li> </ul> <p>2. As a <b>macromolecule</b>, cellulose has <b>few -OH groups available</b> to <b>hydrogen bond</b> with water as most are involved in <b>interchain hydrogen bonding</b>. Thus only the <b>surface of the microfibril</b> has <b>-OH groups</b> that can <b>hydrogen bond</b> with water.</p> <ul style="list-style-type: none"> <li>- Hence cellulose is <b>insoluble in water</b> and the <b>osmotic potential</b> of cells are <b>unaffected</b> by its presence.</li> </ul> <p>3. The <b>meshwork of microfibrils</b> that form the <b>cell wall</b></p> <ul style="list-style-type: none"> <li>- have a <b>porous structure</b> and hence the cell wall is <b>freely permeable to water and solutes</b> and allows <b>movement of substances</b> across the cell wall.</li> <li>- are <b>strong and rigid</b> and <b>distributes stress in all directions</b> to <b>prevent</b> the plant cells from <b>bursting due to osmotic stress</b>.</li> </ul> <p>4. <b>Cellulases</b> that <b>hydrolyse</b> cellulose are <b>found in very few</b> organisms. Thus cellulose cannot be <b>hydrolysed</b> and used as a <b>respiratory substrate</b> and is a <b>good structural molecule</b>.</p>
